The big picture

Fault-tolerant quantum computation: Kitaev's toric code

Kitaev's construction for fault-tolerant quantum computation:

1. Consider a $k \times k$ lattice in the torus and associate the Hilbert space \mathbb{M}_k .
2. Specify a “Hamiltonian” $H: \mathbb{M}_k \rightarrow \mathbb{M}_k$ using “local” features of the lattice.
3. Define as a “quantum memory” the space $\text{Prot}_k \stackrel{\text{def}}{=} \ker H$.

This leads to error correction/prevention implemented on a physical level:

Theorem

For any $k \in \mathbb{N}$ we have $\dim \text{Prot}_k = 4$.

\rightsquigarrow For k large, most errors (modelled by linear operations on \mathbb{M}_k) act either trivially on Prot_k or can be “detected” using various physical methods.

Kitaev's toric code – lattices and the (extended) Hilbert space

Let $k \in \mathbb{N}$ and consider a $k \times k$ lattice embedded on a torus:

Assign to each *edge* a copy of \mathbb{C}^2 and set $\mathcal{M}_k = \otimes_{1 \leq i, j \leq k} \mathbb{C}^2 \otimes \otimes_{1 \leq i, j \leq k} \mathbb{C}^2$.

Kitaev's toric code – vertex actions

Set $\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Given a *vertex* (point in the lattice) v define

$$A_v: \mathbb{M}_k \longrightarrow \mathbb{M}_k$$

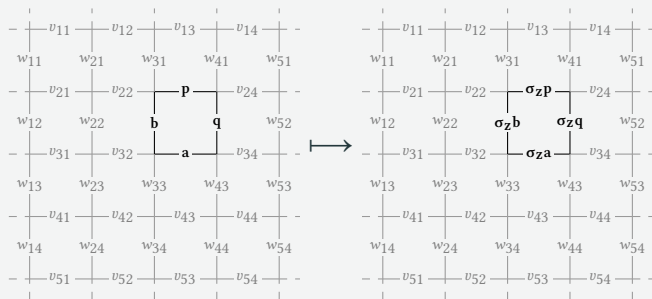

1. Gives rise to a representation $\triangleright_v: \mathbb{CZ}_2 \otimes \mathbb{M}_k \longrightarrow \mathbb{M}_k$.
2. Combining all “vertex actions” leads to $\triangleright: (\mathbb{CZ}_2)^{\otimes k^2} \otimes \mathbb{M}_k \longrightarrow \mathbb{M}_k$.

Kitaev's toric code – face coactions

Set $\sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. Given a *face* (square of the lattice) f define

$$B_f: M_k \longrightarrow M_k$$

1. Can be interpreted as a corepresentation $\delta_f: M_k \longrightarrow \mathbb{C}\mathbb{Z}_2 \otimes M_k$.
2. Combining all “face coaction” leads to a “global” comodule structure $\delta: M_k \longrightarrow (\mathbb{C}\mathbb{Z}_2)^{\otimes k^2} \otimes M_k$.

The local and global module structure of \mathbb{M}_k

Associate to each vertex the face to its “top right” $\rightsquigarrow \{vertices\} \xrightarrow{1:1} \{faces\}$.
 For every such vertex-face-pair (v, f) the vertex action and face coaction turn \mathbb{M}_k into a $D(\mathbb{C}\mathbb{Z}_2)$ -module.

Topological invariance of the protected space

We consider \mathbb{M}_k as a $D(\mathbb{C}\mathbb{Z}_2)^{\otimes k^2}$ -module

Definition

The *protected space* of the Kitaev lattice model is $\text{Prot}_k = \mathbb{M}_k^{\text{inv}}$.

Theorem (Kitaev '97)

For any $k \in \mathbb{N}$ we have $\dim \text{Prot}_k = 4$.

Proof sketch (based on Buerschaper, Mombelli, Christandl, Aguado '18).

Suppose $k \geq 1$. Define an explicit isomorphism between Prot_k and Prot_{k+1} using projectors coming from the Haar integral of $\mathbb{C}\mathbb{Z}_2$. \square

Works for complex semisimple Hopf algebras.

Where to go from here?

Our aim is to generalise this to finite-dimensional non-semisimple Hopf algebras.
This needs three levels of generalisations:

1. lattices on oriented surfaces \longrightarrow Kitaev graphs
2. regular Hopf bimodule \longrightarrow involutive (twisted) Hopf bimodules
3. invariant subspaces \longrightarrow bitensor products

Generalisation 1: From lattices to Kitaev graphs

Each Kitaev graph Γ gives rise to a surface with boundary Σ_Γ and a surface without boundary $\Sigma_\Gamma^{\text{cl}}$:

Generalisation 1: From lattices to Kitaev graphs

Observation: We can increase the number of boundary components of Σ_Γ by gluing a certain graph A to Γ . The surface $\Sigma_{\Gamma\#A}$ of $\Gamma\#A$ has the same genus as Σ_Γ but one more boundary component.

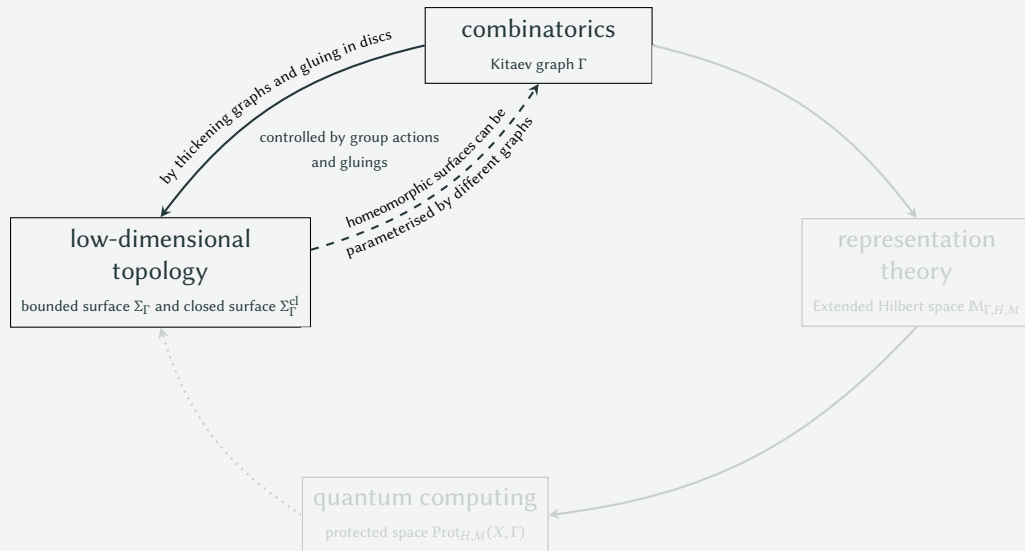

Theorem

There is a group \mathfrak{G} acting on the set of Kitaev graphs such that for all graphs Γ and Δ :

$$\Sigma_\Gamma^{\text{cl}} \cong \Sigma_\Delta^{\text{cl}} \iff \exists a, b \in \mathbb{N}_0 \text{ with } \Delta\#A^{\#a} \in \mathfrak{G} \cdot (\Gamma\#A^{\#b}).$$

The group \mathfrak{G} is connected to the mapping class group of surfaces.
A better (more conceptual understanding) of \mathfrak{G} would be desirable!

Generalisation 1: From lattices to Kitaev graphs

Generalisation 2: Involutive Hopf bimodules

From now on: H is a finite-dimensional complex Hopf algebra.

Generalisation 2: Involutive Hopf bimodules

From now on: H is a finite-dimensional complex Hopf algebra.

Classical: Decorate each edge of a Kitaev graph with the regular bimodule-bicomodule H . Use $S: H \longrightarrow H$ to model the reversal of edge directions.

Problem: $S^2 = \text{id}_H$ is equivalent to H semisimple.

Generalisation 2: Involutive Hopf bimodules

From now on: H is a finite-dimensional complex Hopf algebra.

Classical: Decorate each edge of a Kitaev graph with the regular bimodule-bicomodule H . Use $S: H \rightarrow H$ to model the reversal of edge directions.

Problem: $S^2 = \text{id}_H$ is equivalent to H semisimple.

Definition

An *involutive Hopf bimodule* is a pair of an S^{-2} -twisted Hopf bimodule M together with an involution $\psi: M \rightarrow M$ that intertwines the left and right (co)actions.

Generalisation 2: Involutive Hopf bimodules

Theorem

There is an algebra $\overleftrightarrow{B}(H)$ whose modules coincide with involutive Hopf bimodules.

Generalisation 2: Extended Hilbert space

We fix an involutive Hopf bimodule (M, ψ) .

Construction

Let Γ be a Kitaev graph. The extended Hilbert space is

$$M_\Gamma \stackrel{\text{def}}{=} \bigotimes_{e \in E_\Gamma} M.$$

Generalisation 2: Extended Hilbert space

We fix an involutive Hopf bimodule (M, ψ) .

Construction

Let Γ be a Kitaev graph. The extended Hilbert space is a copy of M for every edge of Γ .

$$\mathbb{M}_\Gamma \stackrel{\text{def}}{=} \bigotimes_{e \in E_\Gamma} M.$$

Generalisation 2: Extended Hilbert space

We fix an involutive Hopf bimodule (M, ψ) .

Construction

Let Γ be a Kitaev graph. The extended Hilbert space is

$$\mathbb{M}_\Gamma \stackrel{\text{def}}{=} \bigotimes_{e \in E_\Gamma} M.$$

For every vertex $v \in V_\Gamma$ and $f \in F_\Gamma$ define algebra maps

$$A_v: H \longrightarrow \text{End}(\mathbb{M}_\Gamma), \quad B_f: (H^*)^{\text{op}} \longrightarrow \text{End}(\mathbb{M}_\Gamma).$$

These maps depend on the “local” structure of Γ .

Generalisation 2: Extended Hilbert space

Generalisation 2: The extended Hilbert space as topological invariant

For Γ a Kitaev graph, set $H_v = H$ for each vertex $v \in V_\Gamma$ and write $\mathbb{H}_\Gamma \stackrel{\text{def}}{=} \bigotimes_{v \in V_\Gamma} H_v$.

Theorem

The local (co)actions turn \mathbb{M}_Γ into an \mathbb{H}_Γ -Yetter–Drinfeld-module.

Suppose the graphs Γ and Δ satisfy $\Sigma_\Gamma \cong \Sigma_\Delta$. Then \mathbb{M}_Γ and \mathbb{M}_Δ are isomorphic as Yetter–Drinfeld modules.

Work by Bene’10, Jackson’18, and Meusburger, Voß’21 suggest that for (certain) M there is a canonical action of the mapping class group of Σ_Γ on \mathbb{M}_Γ .

Generalisation 2: Involutive bimodules and extended Hilbert spaces

Generalisation 3: Bitensor products

Definition

Let $(X, \triangleleft, \varrho) \in \mathcal{M}_H^H$ and $(N, \triangleright, \delta) \in {}^H_H\mathcal{M}$ be right-right and left-left modules-comodules respectively.

1. We write $\pi_{X,M}: X \otimes_{\mathbb{k}} M \longrightarrow X \otimes_H M \stackrel{\text{def}}{=} \text{coker}(\triangleleft \otimes \text{id}_M - \text{id}_X \otimes \triangleright)$.
2. We set $\iota_{X,M}: X \square_H M \stackrel{\text{def}}{=} \ker(\varrho \otimes_{\mathbb{k}} \text{id}_M - \text{id}_X \otimes_{\mathbb{k}} \delta) \longrightarrow X \otimes_{\mathbb{k}} M$.
3. The *bitensor product* of X and M is $\text{Bit}_H^H(X, M) \stackrel{\text{def}}{=} \text{im } \iota_{X,M} \pi_{X,M}$.

If H is semisimple and $N \in {}^H_H\mathcal{YD}$, we have $\text{Bit}_H^H(\mathbb{k}_\varepsilon^1, N) \cong \text{Hom}_{D(H)}(\mathbb{k}_\varepsilon^1, N)$.

This map is particularly interesting in positive characteristic due to its connections with the order of S^4 .

Generalisation 3: Bitensor products and closing boundaries

Let $v \in V_\Gamma$ be a vertex. It has a corresponding boundary component b of Σ_Γ . We think of $\text{Bit}_{H_v}^{H_v}(X, \mathbb{M}_\Gamma)$ as closing the boundary b by gluing in a disc labelled X .

Generalisation 3: The annular graph

From now on: We assume $\dim M^{\text{coinv}} = 1$ and fix a $Y \in \mathcal{M}_H^H$ which “trivialises” the annular graph.

Note: If $\dim M^{\text{coinv}} = 1$, a suitable Y always exists.

Warning: Not all Hopf algebras admit an involutive Hopf bimodule M such that $\dim M^{\text{coinv}} = 1$.

Generalisation 3: The protected space

Definition

Let Γ be a Kitaev graph and $X \in \mathcal{M}_H^H$ and write

$$\mathbb{X}_\Gamma \stackrel{\text{def}}{=} \bigotimes_{v \in V_\Gamma} Z_v, \quad \text{where } Z_v = \begin{cases} X & \text{if } v \text{ is distinguished,} \\ Y & \text{otherwise.} \end{cases}$$

We call $\text{Prot}_M(X, \Gamma) \stackrel{\text{def}}{=} \text{Bit}_{\mathbb{H}_\Gamma}^{\mathbb{H}_\Gamma}(\mathbb{X}_\Gamma, \mathbb{M}_\Gamma)$ the *protected space*.

Generalisation 3: Excision

Recall: Topological features of Kitaev graphs are controlled by the group \mathfrak{G} and iterated gluings of graphs.

Theorem

Let Γ, Δ be two Kitaev graphs, we have a short exact sequence

$$0 \longrightarrow \text{Prot}_M(X, \Gamma) \otimes \text{Prot}_M(X', \Delta) \longrightarrow \text{Prot}_M(X \otimes X', \Gamma \# \Delta) \longrightarrow \text{CBit}_M(X, X', \Gamma, \Delta) \longrightarrow 0.$$

Generalisation 3: topological invariance

Corollary

For any Γ we have $\text{Prot}_M(X, \Gamma) \cong \text{Prot}_M(X, \Gamma \# A)$. In particular, if Γ and Δ are such that $\Sigma_\Gamma^{\text{cl}} \cong \Sigma_\Delta^{\text{cl}}$ then $\text{Prot}_M(X, \Gamma) \cong \text{Prot}_M(X, \Delta)$.

Any surface can be decomposed as a connected sum of tori.
Explicit computations and geometrical interpretation of results?

Thank you
